Research Associate
Summary

The latest data for August 2009 reveals that house prices declined by 25 percent in the Phoenix metro area, which is slightly less than the 28 percent decline for July and 31 percent in June (Table 1). The decline in the index which began in March 2007 has continued for 30 months compared to the 17 month decline in the early 1990s. Preliminary estimates for September and October have prices declining at progressively slower rates, 23 and 20 percent respectively. Since the most rapid declines back in February and March, the index has been declining at a slower rate each month. In contrast to the overall 25 percent annual decline, the August to August decline for lower priced homes was 37 percent compared to 19 percent for more expensive houses. The market wide increase from July to August was less than 1 percent. As the housing market is regaining some measure of stability, changes in the index might be expected to vary between slightly positive and slightly negative each month. For example, the July to August change was positive in four cities and negative in four others so it is important not to read too much into short term fluctuations in the housing market. The total decline in prices from the mid-2006 peak is 47 percent, which breaks down to 60 and 38 percent declines for the lower and higher priced houses, respectively.

The overall median price for sales that were included in the August index was $126,500, up from $125,000 in July. Preliminary median prices for September and October were $130,000 and $131,000, respectively, well above the April bottom, $117,500. Recent increases in prices primarily reflect foreclosed houses that have been purchased by investors and first-time buyers taking advantage of the federal tax credit. However, the large number of foreclosures that are likely to hit the market through 2010 makes it difficult to predict the direction of house prices with any certainty. The median price for lower and higher priced houses in August was $89,700 and $245,000, respectively.

Unlike in the single-family market, the townhouse / condo RSI continues to decline but at a rate that may be leveling off. The decline from August to August reached -36 percent, which was the same percentage as reported last month for July to July. The median price of townhouse / condo units was $99,000 in August with September and October preliminary estimates at $98,700 and $90,000, respectively. However, after several months of relative stability in townhouse / condo median prices, the October decline is not a good sign. Because attached units represent a much smaller segment of the market than detached, single-family houses, there are fewer paired sales and considerably more volatility in the townhouse / condo RSI as can be seen in Figure 4.

#### Regions
Annual rates of decline vary widely across the five regions but the differential is narrowing slightly. The index declined by over 20 percent in the Northeast from August 2008 to August 2009 but by 33 percent in the central region (Table 2). The August decline in the hard hit central region was actually 4 percent less than was reported last month. For the June – August quarter, the index increased by 6 percent, far more than in any other region. While all five regions showed similar dramatic increases in house prices from January 2004 to their 2006 peaks (74 – 81 percent), total price declines through June have varied widely. The Southwest is down the most since the peak, 58%, with the Central and Northwest regions also down over 50 percent, reflecting the severity of the foreclosure problem in those parts of the metro area. Even in the Northeast, which has been the least affected, prices have declined by over 33 percent.

#### Cities
Variations similar to those observed in the regional data are also apparent in the city data (Table 3). The declines in house prices from August 2008 to August 2009 slowed compared to the July data for all cities. In hard hit Glendale the annual decline slowed to 31 percent compared to 34 percent in the last report. Prices have declined by over 50 percent in Glendale, Peoria and Mesa since they peaked in 2006 with substantial declines in excess of 30 percent in all other cities including Scottsdale / Paradise Valley.

Methodology

The use of repeat sales is the most reliable way to estimate price changes in the housing market because the repeat sales approach eliminates the need to deal with the many issues associated with the heterogeneous nature of housing. Repeat sales can be used to measure the price change of the same housing unit over time. A large number of repeat sales over many years can be analyzed to develop a repeat sales index. In contrast, indices developed using regression analysis provide estimates of price changes over time while simultaneously attempting to control for differences in house characteristics, location, demographics and market conditions, etc. within the model. Regression analysis can and does produce meaningful estimates of price changes but the results are not as reliable as those produced using repeat sales data. An even less rigorous approach would be to simply average sale prices by zip code or some other geographic area where the mix of housing sizes and ages, etc. would be different each month. The percent changes based on medians or averages would reflect not only price changes but also differences in the sizes, ages and other characteristics of the houses sold each month.

The W.P. Carey School of Business – Repeat Sales Index (RSI) tracks very closely to the S&P/Case - Shiller index for Phoenix since the same methodology is employed for calculating both indices. The S&P/ Case-Shiller index has been developed for 20 metropolitan areas and is being used as a basis for trading housing futures contracts in 10 of those markets. Any differences that exist between the two indices are probably due to the way the data has been cleaned prior to the calculation process. The S&P/Case-Shiller index is proprietary so the cleaning procedure used in connection with that index could not be completely duplicated. However, following S&P/Case-Shiller, the cleaning process used with the ASU - RSI excludes pairs where the first sale involved new construction and pairs where sales occurred within six months of each other. Sale pairs with extremely high or low annual rates of price change are excluded since at least one of the transactions may involve a data error. The same justification is used to drop sales with extremely high or low prices or prices per square foot prior to matching the sale pairs. A more detailed explanation of the data cleaning and calculation process is contained in the ASU-RSI Methodology Report.

The house price data used in the S&P/Case-Shiller index starts in January 1989. Beginning with January 1990, the percent change from the same month in the previous year is reported. The ASU – RSI also begins with January 1989 data so the same percent change calculation also begins in January 1990 and is reported for each month since then. There is seasonality in house price data so month to month changes may not accurately reflect changes in market conditions and would cover a very short time period. Calculating a percent change from the same month in the previous year controls for whatever seasonality may be present in the data. Annual rates of change typically are thought of applying to a calendar year but in this report the annual rates that are reported would
be measuring change over the preceding twelve months. To smooth the index, data is included in calculations for the current month and the next two months before it is reported. This means that the rate of return calculated from each sale pair is included in calculations for a total of three months before it is published, which accounts for the difference between the date on the report and the ending date on the graphs.

The S&P/Case-Shiller index is published only for the entire Phoenix metro area. One major advantage to the ASU-RSI is that in addition to the overall index, indices have been calculated for higher and lower priced houses and for smaller geographic areas (regions and selected cities). Price changes for the attached portion of the housing market (townhouse / condominiums) are also presented in a repeat sales index using the same methodology and an index is also estimated for higher and lower priced single-family detached houses. The monthly data are divided into two groups based on the median price of all single-family houses sold. Sales are then paired within each of the two data sets and a repeat sales index is calculated. The metro area has also been divided into five regions and an index has been calculated for each. All repeat sales used in the metro index are included in one of the five regional indices. Indices have also been calculated for eight individual cities where there are a sufficient number of repeat sales a reliable index to be estimated. A list of the cities included in each region is in Table 4.

The graphs contained in this report show the annual rate of change in house prices for the Phoenix metropolitan area on a monthly basis as well as median single-family house prices. Figures 1 and 2 compare the change in the overall, lower and higher priced indices to the overall trend in the index, where the trend was estimated based on the index from January 1989 through December 2003. Figure 3 makes the same type of comparison using the median price of single-family sales that were used to form sale pairs for the current month, not the median price of all sales that occurred during the month. Since each index is a moving three month average, preliminary estimates of the index and future median prices for the entire market are included for the next two months (August and September) in Figures 1 and 2. Figures 4 and 5 include the new townhouse / condominium RSI and the single-family RSI presented earlier in Figures 1 and 2. Figures 6-13 contain eight graphs that cover two time periods. Four of the graphs present the price changes from January 1990 through August 2009 while the other four graphs cover the current housing cycle beginning in January 2004. Due to data limitations, a reliable index for Gilbert could not be calculated until January 1999 so the annual change for Gilbert in Figures 8 and 9 starts in January 2000.
